Definition of terms

DEFINITION OF TERMS

Nominal Resistor Value (R_N): Nominal (printed) resistor value, i.e. 22R (value of the order).

Absolute Resistor Value: Real resistor value of the resistor, i.e. 22R0253.

Tolerance: Max. allowed deviation of the absolute resistor value from the nominal

resistor value in percent from the nominal resistor value.

(delivery tolerance), i.e. 22R ±1%

Accuracy: Resolution / number of digits from the mantissa of the nominal resistor

value, i.e. 5K045 (4 digits accuracy). The accuracy is not the tolerance

even if there is a cohesion.

Stability: Max. allowed change of the absolute resistor value depending from time

and stress. Normally it is mentioned in percent from the absolute resistor

value at t = 0 (reference value).

Temperature Change: Change of the absolute resistor value dependency of the temperature at

the resistance element. It is normally mentioned in ppm (parts per million) of the absolute resistor value at the reference temperature T_{α}

(relative change of temperature dR/R).

Temperature Coefficient (TC): Relative change of temperature of the absolute resistor value at

temperature T relative to the change of temperature (T - T_0). For Ultra-precision resistors the reference temperature T_0 is 25°C.

It is stated in ppm/K.

TCR-Alignment (Tracking): Max. allowed TC difference of different resistors. (i.e. double-resistors,

pair resistors or networks)

Power Dissipation: When applying an electric voltage in a resistor, the energy is converted

into heat. The result of the energy per unit time is the power dissipation.

 $(P = W / t, P = U * I, P = R * I^2, P = U^2 / R).$

Depending on the heat removal, there is a temperature rise of the

resistance element.

Inherent Temperature: Real temperature of the resistance element.

The inherent temperature is the sum of the ambient temperature and the additional temperature of the power dissipation. (excess temperature dT_p).

Limiting Temperature: Max. allowed inherent temperature in exceeding the limiting temperature

it is possible to have non-reversible alteration of the resistance, a change

in it properties or its demolition.

Nominal Power Dissipation: Max. permanent allowed power dissipation without exceeding the

limiting temperature of the resistance. The nominal power dissipation

mentioned in the specifications belongs to these conditions:

- Free-standing assembly.

- Ambient temperature of 70°C without additional cooling or,

- Assembled on a heatsink with optimal fixed mounting (pressurized and

use of a heat conduction paste).

Thermal Resistance (Rth): Factor of proportionality between power dissipation and over-temperature

 R_{th} = dT / P. The specifications mentioned in the data sheet for heatsink mounted resistors (R_{thi-c}) are defined as thermal resistance between the

resistance element and case bottom plate.

Impulse Strength: Max. allowed short-duration (impulse) electric energy, without exceeding

the limiting temperature.

Limiting Voltage: Also referred to dielectric strength; max. allowed voltage applied to the

resistor.

Limiting Current: Max. allowed current through the resistor.

Insulation Strength: Also referred to breakdown rating; max. allowed voltage between the

resistance element and the environment (i.e. chassis or heatsink).

Standard Conditions: Measurement conditions for defining the absolute resistor value, tolerance

and stability of the resistor. In the laboratory and production process the

reference temperature is 25°C ± 2°C.
